Using tip and whorl formation in the marine alga *Acetabularia mediterranea* as an example, we investigate the nature of the spatial ordering which arises from  $\text{Ca}^{2+}$  regulation of the viscoelastic properties of the cell cortex. From a survey of the empirical information available on the effect of free  $\text{Ca}^{2+}$  on the elastic and viscous properties of the cell cortex, and on the mechanisms of strain-induced  $\text{Ca}^{2+}$  release, we derive a set of coupled, non-linear equations using first order theory of elastic and viscous response to stress fields, in effect extending previous work of [Odell \*et al.\* \(1981\)](#) and [Oster & Odell \(1985\)](#) in this regard. Calculations assuming one-dimensional geometries show that bifurcations to relevant spatial patterns can occur in the strain field in the cortical cytoplasm. The secondary effects of such patterns and the experimental implications of the proposed mechanisms are discussed. Finally, some remarks are made relating to a comparison of the strain field approach and that using diffusion-reaction mechanisms.
