### Abstract

Rapid progress has been made in the last decade in the area of the fundamental mechanisms of electrical relaxation and ionic transport in ionically conducting glasses. Many new experimental findings and computer simulations have become available during this period. These more recent developments should not be viewed as overshadowing the importance of earlier works. Instead, many earlier works, having laid the foundation and paved the way for the recent developments, are of immense importance. The phenomenologies that have been firmly established and the critical experimental facts which have been found will be the subjects of this review. One purpose of this work is to promote interest and debate among workers in this field. Hopefully, this will lead to some consensus among workers in the field on a list of critical experimental facts. For theories proposed in the future, these critical experimental facts can be employed

collectively as an acid test of whether the theory is viable.
