Abstract

Inhibition of the aspartyl protease BACE-1 has the potential to deliver a disease-modifying therapy for Alzheimer's disease. Herein, is described the lead generation effort which resulted, with the support of X-ray crystallography, in the discovery of potent inhibitors based on a hydroxy ethylamine (HEA) transition-state mimetic. These inhibitors were capable of lowering amyloid production in a cell-based assay.

Graphical abstract

The discovery of novel BACE-1 inhibitors based on a hydroxy ethylamine (HEA) transition-state mimetic is described: X-ray crystallography facilitated the rapid optimisation of a micromolar hit and led to inhibitors capable of lowering amyloid production in a cell-based assay.

Compound **22**
BACE-1: IC₅₀ = 13 nM
A β 40: IC₅₀ = 310 nM
