## Abstract

The photosynthetic conversion of sunlight energy into algal biomass in large-scale outdoor cultures is controlled by the availability of sunlight, the photosynthetic machinery of algae, nutrients, temperature and the design characteristics of the culture system. For the situation in which light is made the growth rate limiting factor, there is an upper limit in the light conversion efficiency of a large-scale culture, which translates to a maximum potential yield of 30–40 g dry wt m<sup>2</sup> day<sup>1</sup> under ideal sunlight conditions. In practice, the best yield data for outdoor cultures in various locations in the world has been 30–40 g dry wt m<sup>2</sup> day<sup>1</sup> for short periods and considerably less for longer durations. The development of large-scale mass cultures involves many considerations, but the two major design parameters for optimizing yields at a particular time of year are the flow rate through the culture and the depth.
