Publisher Summary

This chapter presents nuclear magnetic resonance. High-resolution, nuclear magnetic resonance spectroscopy shows powerful and applicable physicochemical techniques for the investigation of organic molecules. Proton magnetic resonance spectroscopy offers to carbohydrate chemists a method both for determining the configuration of unknown carbohydrates and for ascertaining the conformations of known carbohydrates in solution. This chapter represents no more than an interim report on the proton magnetic resonance studies of carbohydrates, because there are increased availability of instruments and the development of higher resolution spectrometers. The Boltzmann distribution of nuclei between the two energy-levels is a function of both the strength of the static magnetic field and of the temperature, and it results in a very small excess in the lower energy level. For continuous absorption of radio-frequency energy, the relaxation processes return nuclei to the lower energy level at least as rapidly as they are excited to the higher level. The screening constant depends on the chemical bonding of the proton, and the correlations are established between the electron distributions of compounds and their proton resonance frequencies.
